The New Instructional Leadership:
Creating Data-Driven Instructional Systems in Schools

Abstract

The recent demand for schools to respond to external accountability measures challenges school leaders to create school instructional systems that use data to guide the practices of teaching and learning. This paper considers how local school leaders build *data-driven instructional systems* (DDIS) by developing new programs and using existing school functions to create an information flow through a school. The paper considers how leaders work with teachers and students to create DDISs to intentionally and systematically improve student learning. The paper begins by presenting a theoretical and analytic framework to understand how the systems that local school leaders create to develop a DDIS to facilitate an “information flow” about student achievement in the school. The first part of the paper presents the DDIS as a six-step cycle involving 1) data acquisition, 2) data reflection, 3) program alignment and integration, 4) instructional design, 5) formative feedback and 6) test preparation. The second part reviews data collected in a year-long study of four schools in terms of the DDIS cycle to describe how the leaders structure opportunities to engage in data-driven decision making. The data provides rich examples of how schools facilitate and impede the flow of student achievement information, and problematize the notion of a simple definition of data-based decision making in schools.
Introduction

In June 2005, the New York City Public Schools announced that 5th-grade test scores had made impressive gains across the city schools – 15.2 percentage points (in students testing proficient and above) in math, and nearly 20 percentage points in reading. Some of the most impoverished, lowest achieving schools were responsible for the largest gains. While politicians and policy makers wrangled to claim credit or to question the legitimacy of the results, school leaders, teachers, parents and students offered a more simple explanation: “hard work.” But what did they mean by hard work? Leaders and teachers emphasized “a relentless focus on literacy and math” and a “ceaseless scrutinizing of tests, quizzes and writing samples” to understand what students didn’t know (NY Times, June 12, 2005). Others highlighted after school tutoring and preparation, improved attendance, pre-kindergarten, smaller classes, fear of grade retention, community outreach and intense political pressure to succeed. However, neither leaders, teachers, nor parents could “agree on any one primary reason for the gains.” In part, this was because there was no “one primary reason,” no silver bullet, to explain the gains. The gains did not result from a particular program, a new policy, or new personnel. Rather, the broad improvements in student learning achieved in New York and in schools across the country were the results of many factors designed to work together in complex instructional systems. The capacity of school leaders and teachers to reshape moribund schools into organizations able to respond to the feedback of standardized testing represents a significant step forward in our understanding of school leadership practice. The purpose of this paper is to provide a framework, the data-driven instructional system (DDIS), to tell how school leaders develop this new organizational capacity, and to discuss how well the framework captures the practices of innovative school leaders like those in the New York to outline the new instructional leadership.

The work of school leadership is undergoing a revolution. The recent policy press for standards and accountability has led policy makers and the public to hold teachers and schools responsible for improvements in student learning. While teachers are ultimately responsible for improving student learning in schools, changing the organizational conditions for improvement across schools is the central task of school leaders. The new
instructional leadership pushes beyond the debates between instructional, managerial and transformational practice to a new conception of creating accountable learning systems in schools. And, in many schools throughout the country, evidence is mounting that leaders are helping schools change practices to improve student learning in terms of standardized testing. The two-part question we address here is: what are successful school leaders doing to systemically improve student learning, and how can we communicate these innovative practices to leaders interested in learning?

The initial stage in this change has been widely characterized by researchers and educators alike as a move toward data-driven decision making spurred by No Child Left Behind (2001). Recent discussions on data-driven decision making have focused on the generation, analysis and use of student achievement data with teachers as the primary response to accountability demands (Bernhardt, 1998; Holcomb, 1999; Johnson, 2002; Love, 2002). State educational leaders have rushed to provide the disaggregated student data in terms of achievement tests calibrated to content standards. Private vendors make millions with the sale of data warehousing and reporting systems to sort through the data (Burch, 2004). Local districts and service agencies hire consultants for data analysis workshops and data retreats to make sense of achievement data in terms of local priorities. Schools shop among comprehensive school reform plans and packaged curricula already coordinated with state learning standards and assessments. The seemingly very recent debate about the legitimacy of standardized testing as a measure of student learning has quickly given way to an onslaught of interest in helping schools meet the challenge of improving student test scores across systems. When connected together, tests, standards and policies comprise accountability systems. Hanushek and Raymond (2002) argue that these accountability systems will help reshape local practices:

[A] focus on student outcomes will lead to behavioral changes by students, teachers, and schools to align with the performance goals of the system. Part of this is presumed to be more or less automatic (i.e. public reporting of outcomes will bring everybody onto course with those outcomes). But part also comes from the development of explicit incentives that will lead to innovation, efficiency and fixes to any observed performance problems. (p. 81)
The inability of schools to adapt easily to the demands of accountability systems suggests that such systems exist at multiple levels. From the perspective of schools, these policy initiatives constitute external accountability systems. The central problem for guiding systemic change is that schools already have robust local driven accountability systems. Implementing the policies of the external system in schools is not merely a matter of providing the proper incentives to plant on clear land. All schools already engage in many forms of data-driven decision making that rely on quantitative information about student attendance, grading, budgets and student placement information and qualitative information on teacher, student and parent reputations. Taken together, these data comprise robust internal accountability systems that already shape and guide complex systems of practices in schools. Internal accountability systems enable schools to respond to emergent challenges while maintaining stable, persistent structures. These internal accountability systems have evolved along with the traditional practices of schools, and help form school cultures that provide seamless feedback on core instructional and managerial practices. The press for data-driven decision making, then, is not a call for schools to begin to use data, but a challenge for leaders to reshape the central practices and cultures of their schools to react intentionally to the new kinds of data provided by external accountability systems.

Thus the heart of the new instructional leadership is the ability of leaders to shift schools from cultures of internal to external accountability. Data-driven decision making can produce its intended effects only if supported by organizational capacity that allows school teachers and leaders intentionally change instructional practices in the face of new information. As described by Mark Wilson (2004), coherent accountability systems depend on establishing two-way information flow connecting classroom practice and external accountability measures. In order to realize this translation function, leaders need to re-frame the traditional practices of schools to make sense in a culture of external accountability. This new work, to be sure, draws on traditional practices of program and teacher evaluation, curriculum design, professional development, and creating cultures of learning. However, these old tools and practices need to be used to challenge the status quo organization of traditional schooling. Leaders working in schools traditionally characterized by loose coupling of administrative and teaching practice, teacher
autonomy, individualized professional development and unmonitored instructional quality are now faced with policy expectations that push for tightened coupling of teaching and leadership, teacher collaboration, professional learning on instructional goals and closely monitored instructional outcomes. The new instructional leadership will require knowledge and frameworks to guide leaders in creating schools that systematically improve student learning. Leaders will need to be able to work with teachers to help students test well while not reducing learning to testing, and will need to be able to justify changes in instructional and personnel practices to an increasingly well-informed community.

Data-Driven Instructional Systems

In this paper we present a theory for how to understand the new instructional leadership—creating data-driven instructional systems in schools. We realize that, as usual in educational research, practitioners are not waiting around for researchers to provide tools for solving the problems of practice. To be sure, some of these new solutions “game” the learning process by emphasizing the requirements of testing over authentic learning. But to characterize all efforts to improve learning through accountability to standardized testing in terms of cheating misses the story of leaders who are reinventing instructional leadership and reframing what learning means in our schools. Our research addresses the nature of these new practices with a blend of deductive and inductive process. We have developed a Data-Driven Instructional Systems (DDIS) model to describe the structures and practices leaders use to develop a school’s capacity to use data for instruction. Using research in distributed leadership and organizational learning theory, the data-driven instructional system framework describes how leaders created systems to re-culture schools for accountability. A successful DDIS helps to translate summative achievement test data into formative data teachers and students can use to improve teaching and learning. The DDIS framework we describe here was developed from a review of the literature on data-driven decision-making and refined in the analysis of our fieldwork. We begin the paper by presenting the six functions of the DDIS and discuss how these functions operate together to translate summative data to formative information. We then present a preliminary analysis of data
we have collected from four schools over the past year to illustrate how the DDIS framework functions in schools. We conclude with a discussion of relative merits of shifting instructional leadership from traditional functions to creating DDISs in schools.

**Distributed Leadership**

Distributed leadership theory has recently emerged as an analytical tool for understanding leadership practice in complex settings (Spillane, Halverson & Diamond, 2004; Bennett, et.al., 2003). The theory is a descriptive tool that considers how leadership tasks are distributed socially and situationally in schools. The central task of instructional leadership is to create the conditions for improving teaching and learning in schools. While social distribution addresses how leaders delegate and share tasks across actors, the situational distribution of leadership considers how leaders structure contexts to support intended practices (Halverson, 2003). The situational and social distribution build on each other: social task distribution helps to create the structural supports, which, in turn, establish the traditions and the culture of practice in schools. The concept of artifact plays a key role in understanding how professional community is developed in schools (c.f. Norman 1988; Simon 1996). From a school leadership perspective, artifacts refer to designed programs, procedures and policies intended to shape or reform existing organizational practices (Halverson, 2001; Halverson & Zoltner, 2001). Taken together, the network of artifacts in a given school establishes a *system of practice* (Halverson, 2003). Tracing the development and interaction of artifacts in a local system of practice provides a path for researchers and practitioners to access the elusive context of practice for teaching and learning.

Data-driven instructional systems are thus certain kinds of systems of practice dedicated to making summative data on student learning useful for improving teaching and learning in schools. Considering data-driven decision making from a distributed leadership approach suggests that we first identify the key tasks involved in a DDIS, then identify the structures leaders develop and use to share tasks among people and across artifacts. Following the DDIS development in schools provides access to the obscure and ill-defined process of capacity development for data use in schools. The resultant stories
of how leaders and teachers developed organizational capacity open a window into how leaders frame and solve the complex problems of the new instructional leadership.

Organizational learning theory

A data-driven instructional system helps translate the results of summative testing into formative information teachers can use to improve instruction. The system needs to access data, help teachers and leaders reflect on what it means, plan and determine what needs to be done, and assess the results of the plan. In many ways, a DDIS reflects the central concepts of the organizational quality movement inspired by W. Edwards Deming. Deming’s ideas inspired organizations to move beyond bottom-line results to focus on embedding quality cycles throughout the organization (c.f. Walton, 1986; Deming, 2000). The quality approach has been simplified in terms of embedding redundant plan-do-study-act cycles within organizational processes to ensure that feedback on core practices is integrated into the system. Programs such as the Baldridge National Quality Program (http://www.baldrige.nist.gov/) help translate the central ideas of the quality movement into school evaluation.

The concept of systemic feedback on core processes is central to the quality movement. Feedback systems are essential for developing organizations that can learn from prior practices and intentionally shape practice to achieve anticipated ends (Senge, 1990; Senge, et. al. 2000). Feedback processes translate organizational outputs into useful information that guide subsequent input behaviors. The lack of widely accepted output measures has been a primary obstacle in creation of systemic feedback processes in schools, making it difficult to generate legitimate output information to be used as feedback. The recent press for accountability through standardized testing can be seen as an effort to provide legitimate output measures for school. However, even with access to legitimate feedback information, feedback in human systems cannot be reduced to a mechanical procedure for incorporating appropriate information into organizational processes. Ilgen, et.al. (1979) emphasized the role of individual cognition and sense-making by describing how organizational feedback must perceived and accepted as valid, then the recipient must be motivated to respond in ways that improve the process. Ironically, the more recipients are known for their ability to give advice and guide
learning, the more willing they become to circumvent the implication of critical feedback (e.g. Argyris, 1991). Nadler (1978) noted that the feedback process gets more complicated in group processes where individuals struggle to understand the meaning of feedback in terms of individual and organizational goals.

Feedback systems require component functions that gather relevant data, provide opportunities to sort through the data, and structures to introduce findings back into the core organizational processes (Watson, 2005). The traditional loosely-coupled structures of schools have worked against either generating or integrating feedback about core instructional across classrooms in schools (Weick, 1995). Separating instructional from administrative practices effectively creates multiple information loops for organizational control and for teaching and learning within schools (Meyer and Rowan, 1983; Thorn, 2001). The traditional isolation of classroom teachers from each other further fragments the potential for a common vocabulary of information exchange, and the traditionally severe demarcation between teacher evaluation and teacher learning prevents school leaders from bringing organizational measures of student learning to bear for individual teachers. Because the feedback systems include multiple measures of organizational effectiveness, student learning, program design and teaching practice, the effect knitting these diverse kinds of knowledge together will tighten the coupling of leadership and teaching practice.

Data-driven Instructional System Framework

A DDIS builds a feedback system as a form of organizational capacity necessary to meet the accountability demands for student learning. In building a DDIS, leaders use a variety of artifacts to reshape local accountability systems in order to satisfy the demands of external accountability systems. Our model data-driven instructional system includes six component functions: Data Acquisition, Data Reflection, Program Alignment, Program Design, formative Feedback, Test Preparation. Leaders and teachers work to help these functions to come together to translate student achievement data into useful, classroom knowledge to inform teaching and learning.

1. **Data Acquisition** refers to processes to seek out, collect, and prepare information to guide teaching and learning. The primary data collected and organized is
standardized student achievement test scores. Many other types of information are required to guide teaching and learning, including:

- Guidance information (Student placement and behavioral records)
- Student demographics
- Classroom grades
- Teacher personnel and observation
- Community survey data
- Budgetary information
- Master schedule and calendar information
- Curricular information
- Technological capacity

Figure 1: The Data-Driven Instructional System Model

Data storage (data warehousing) and reporting capabilities are also included in data acquisition. Relevant data are often housed in different organizational locations and in different formats, and streamlining data access can run aground on political issues positional access to certain kinds of information. Local data acquisition systems often build on existing district and state accountability systems. However, the need for specific information on student performance has
led many local school leaders to create custom local data systems, and the NCLB push has led vendors to address this need with a variety of data storage and analysis products.

2. *Data Reflection* refers to processes developed to make sense of student learning data that result in goals for improving teaching and learning. While reflection is a constant and unpredictable consequence of working in data rich environments, the data reflection component of the DDIS refers to structured opportunities for teachers and leaders to collaboratively make sense of data. These structured sense-making sessions can be organized as whole-school sessions, or by grade or subject level teacher meetings. The duration of reflection sessions varies as well – some schools hold one-time whole school meetings; others meet regularly through the school year. Successful data reflection involves problem-framing and concludes with the determination of goals for a plan of action.

3. *Program Alignment* involves processes to make the school’s instructional program congruent with relevant content and performance standards as well as what is taught in classrooms in order to improve learning and to meet student needs. Program alignment activities take place at several levels. Alignment practices ensure that the school curriculum addresses content standards through grade and subject-level meetings. Alignment activities also include teacher and peer evaluation to ensure that what is in the curriculum is what is taught in classrooms. Finally, program alignment considers how non-curricular initiatives such as guidance and support programs, professional development, and community outreach activities to make sure that existing school commitments address the concerns for which they were designed. Since school districts often provide alignment tools or mandate standard curriculum for alignment purposes, the story of alignment involves school interaction with external agencies. Program alignment is a key aspect of planning and program evaluation.

4. *Program Design* is how a school acts on perceived instructional needs through the creation or adaptation of curricula, pedagogies, student service programs and instructional strategies in order to improve student learning. Program design addresses the range of policies, programs and procedures adopted or designed by
the school to address recognized problems. Instructional program design can be addressed at instructional issues that meet the needs of groups of students through curriculum design, or student-level programs that evaluate and determine the needs of individual students. The financial capacity to acquire and maintain programs, as measured by budgets and grants, is also an aspect of program design. Taken together, programs designed by the school can have varying degrees of coherence as evidenced by the compatibility of internal characteristics or their perceived coherence by staff.

5. Formative Feedback produces learner-focused iterative evaluation cycles designed to create ongoing timely flows of information used to improve both student learning and instructional program quality across the school. The generic notion of formative feedback is information useful for improving teaching in order to help the learner take ownership of learning. Formative feedback in a DDIS is concerned to improve program design. Formative feedback can include information on student learning or teacher practice, but it becomes part of a DDIS when information is discusses about teacher practice in implementing programs. Formative feedback is also different from data acquisition and reflection. Although these functions also include reflection, formative feedback refers specifically to information gathered about the programs put in place at the school. We hypothesize that the distinction between data acquisition and reflection and formative feedback becomes increasingly blurry over time in mature DDISs.

6. Test preparation includes activities designed to motivate students and to develop strategies for improving performance in taking state and district assessments. Test preparation can range from teaching students about the format of tests, developing skills specifically outlined by standardized tests, covering test topics which data suggests school/district students are demonstratively deficient, sharing habits with students which have been shown to improve test scores (i.e. eating good meals). Although denounced by some researchers as efforts to "game" the testing system, many schools see test preparation as an extension of their program design efforts specifically designed to help make children comfortable with increasing testing time and pressure.
Our concept of a data-driven instructional system in schools builds on recent proposals for how schools should use data to achieve results in student achievement. (e.g. Bernhardt, 1999; Love, 2002; Schmoker, 200x) These models include guidelines for assessment, goal-setting, analysis, implementation and feedback. However, a distributed leadership perspective suggests that leaders take an active role to link these components into structures through which information can flow from tests to teachers in a school. A distributed leadership perspective also suggests that leaders need to take account of the existing system of practice in building DDIS components. Schools already have artifacts that collect and distribute data; the task of leaders is to make sure these existing system components talk to each other as much as it is to design and implement new component artifacts. We now turn to a discussion of the data we have collected over this past year to illustrate how the DDIS components function together to improve student learning in schools.

Data-Driven Instructional Systems In Action

Over the past year we have engaged in a National Science Foundation-funded research project designed to study how leaders create systems to help teachers use data in their instruction. In the first year of our study we focused on how DDIS components functioned in four Midwest elementary and middle schools identified by improving test scores and their reputation for having leaders who used data well with teachers. After consulting with educational leaders at the university, state and district level, we narrowed our sites to 8 schools recognized for strong leadership and data-driven decision-making. Schools with the strongest record of improving student achievement played in deciding role in site selection. We narrowed our list to the 4 schools in Table 1.

We collected interviews and observation data as well as a variety of artifacts at each of the schools. We conducted structured interviews (Appendix A) of the principal and the formal and informal leaders as nominated by the principal and through our fieldwork. We observed and took field notes on faculty meetings, professional development sessions, data retreats, and other important events as identified by the staff. We collected artifacts such as school improvement plans, staffing charts, budgetary information and parent/community handouts. To make sense of the over 1000 pages of
fieldnotes and artifacts collected, we used a qualitative data analysis program (NVIVO) to code our data in terms of an analytical scheme based on the DDIS framework (Appendix B). After an initial pass through the data using the DDIS coding framework, we refined our schema in order to catch the nuances of the practices we observed. The first report of the data that follows will help us to test the validity of the DDIS, and to refine the model so that it better describes the practice of successful leaders.

**DDIS functions in schools**

We found clear evidence of the operation of each function within the DDIS model in each school. Although each school collected and used data, aligned, redesigned and analyzed their instructional program, and provided test preparation guidance, we found wide variation on how the functions were developed in each school. Here we consider the ways in which the four schools demonstrated the six DDIS functions in practice.

Data Acquisition

A central assumption of a DDIS is that data fuels the improvement process. The data acquired must have the potential to inform teaching and learning, but it need not be limited to test score results. As a district official told us:

>[T]he message that we give to schools is that they need to use student performance data from a variety of sources in order to put together the whole picture of student achievement. We don’t want them to focus solely on standardized test scores as they develop their educational plans, even though
those are the most readily available because they are all electronic and the central office can neatly provide them with reports.

While accountability demands encourage the reduction of data to simple test scores for reporting purposes, the school leaders impressed upon us the importance of collecting a much wider variety of data to improve instruction. The teachers and administrators in the schools realized that improving learning required a more sophisticated definition of data. As the same official expressed:

We do want them to look at [test scores] and understand student performance as measured by standardized tests. We also want them to develop systems internally so that they can use performance data from the classroom in an ongoing way to monitor to see whether or not their kids are on course to meet objectives that they have in their educational plan.

We found that data acquisition consisted of a number of subsidiary functions: data collection, storage, and reporting. Here we review the different aspects of the data acquisition process:

**Collection.** School leaders had access to standardized test scores through paper reports sent to the schools and through on-line data portals maintained by the state test publishing company. In addition to summative test scores, each school collected information on attendance, student and community demographics, discipline referrals, expulsion and retention records, and student grades. The schools also collected a variety of information about the instructional program, such as student writing samples, and teacher and class observations, survey-based climate data, and daily student assessments (usually in literacy). The district office played a central role in data collection three of our four schools. These offices collected district and state assessment information and made it available to principals online.

The schools realized that data generated for administrative, accountability purposes were insufficient to support local change processes. Each school had developed a number of different internal data acquisition systems to guide instructional improvement. Harrison school, for example, has exploited the rigorous data collection system in its Direct Instruction (DI) program to generate data about teaching and learning. Harrison’s principal describes how the DI helps guide her data collection:
[W]e've really become quite talented I think at data collection, particularly with the use of Direct Instruction, because (data collection) is an integral part of that program. The teachers . . . daily [are] collecting data on students, on how they're performing, on how they're doing. . . . We do check-outs, whether or not they pass tests after every five lessons in Direct Instruction, so all of that information gets collected, it gets compiled.

Another Harrison staff member in the school noted that, in addition to the data collected after every five lessons, the teachers maintain daily records of student learning:

Well, there's lots of data that teachers keep in terms of Direct Instruction. So there's the weekly checkouts, and there's the responses to the daily textbook and the daily workbook and all of that's recorded and turned in weekly. .

In addition to the data generated within the school program, the Walker school has turned to the Northwest Evaluation Association’s Measure of Academic Progress (MAP) program, a computerized adaptive test students can take during the year that makes timely student achievement available to the school to generate additional data.¹ (More about MAP below in the Formative Feedback section).

In addition to systems to recording student achievement data, our schools have developed systems for managing attendance and discipline data. One associate principal articulated how the school records the attendance data as well as the connection between attendance and learning:

There's a log that we keep in the attendance room and we look at about every two weeks or so to see if we have any updates and whenever we have a situation, we log it into this record. Our student management record system is what records student attendance and grades, and I review weekly reports of how we're doing with student attendance because when we're having students coming into class late, it is a disruption to the teaching and learning that should be expected to begin immediately once the class gets underway.

¹ Measures of Academic Progress (MAP) is a computerized adaptive testing program published by the Northwest Evaluation Association developed in terms of state standards designed to provide formative information for schools on how students are progressing toward state achievement standards. The MAP testing program at Walker will be discussed further in the Formative Feedback section of the DDIS (pp. xff.)
Malcolm school developed a robust system for recording student discipline data to address the influence of student behavior and school environment on teaching and learning. Their Respect and Responsibility (R&R) program using a spreadsheet system to record and track behavioral data. The school’s principal reviews the data during a weekly meeting with the administrative team, and at any other time. The R&R system is an example of a sophisticated local data collection system that does not include test scores and that serves as the starting point for a Data-Driven Instructional System addressing student behavior.

Storage. Once data are collected, they must be made accessible for leaders and teachers. We observed a range of low- and high-tech data storage practices ranging from filing cabinets and binders to sophisticated off-site data warehouses. Three of our schools relied on a significant district investment in data warehousing technology for data storage purposes. Still, each of the four school principals relied primarily on low-tech printouts and notebooks to keep track of data relevant to the school program. Aside from standardized attendance and budgeting programs, a school’s local data storage system generally operates independently of the district data system. The mismatch between high-tech district storage and low-tech local collection and storage meant a) that local leaders needed to be literate with both systems, and b) that principals acted as data conduits between the district and the schools.

One district leader proposed a bridging system:

[W]hat I think would be really cool is if we had one super application and achievement management system that would pull them all together—that would tie the curriculum that teachers deliver daily to the district's learning targets and the state's standards to performance on state and local assessments so that the full picture is there. You could put classroom assessment performance in there. You would have standardized test performance information—you would have curriculum that you delivered and it would really promote this alignment of curriculum, instruction and assessment that we're advocating at the central office, but we don't have a good vehicle for supporting that at the school level.

The fully integrated data system of which some leaders dream is far from being achieved, but some have recognized its value and have made some degree of progress. However, even though principals talked about participating in dual information systems, the
complaints about the existence of dual systems came mainly from the district level. This may be because local school leaders realized that control over information storage would ultimately determine the kinds of information schools could legitimately collect. Integrating all relevant information into a single system would likely reduce the autonomy and flexibility of local actors to acquire the information necessary to address emergent problems, and increase external control over local schools.

Reporting depends on the kinds of information desired by school leaders to improve instruction. Thus the kinds of reports requested by leaders and teachers provide a good reflection of the problems they perceive as worthy of addressing. In our observation we found that data reporting was often an interactive, dynamic process. In low-tech districts, data reporting consists of interpersonal interactions with people in charge of data storage. In Pearson school, for example, the principal and several lead teachers meet regularly to develop reports on student learning collected through regular testing and anecdotal information. The discussions surrounding report generation and results provide an occasion to develop shared understanding of purpose and strong professional community among the leadership team. Another school developed what they call a “Critical Index” in order to report weekly data. An administrator at the school collects the data and compiles the Critical Index every month in order to expedite its review by the principal. The principal explains the origin of the Critical Index and the recognition it has since received:

[O]ther schools have used our Critical Index and they've used some of the other sheets that we've used to collect data, because they've used it as an example. And that was really developed by our needs, and looking at the needs of what do we need to find out for information that will help us improve, and then how can we develop this form?

In high tech districts, data reporting is guided by district-designed query templates accessible on-line. One district has assembled hundreds of online report templates for principals and provides training to principals to access the system and make sense of which report to use. These online tools can be used to collect reports according to customized search terms, including demographic limiters, academic subject or standard, and year. In some districts, principals also have liaisons in the central office to help
procure data reports. The reports are then used to structure conversations with staff. The customized searches refine the data to only those issues that the principal hopes to know about at the moment. The “data reduction” function served by district reports can be very important for principals who can feel, as one admitted to us, “somewhat overwhelmed with data.”

Data Reflection

Making sense of data is a critical function of a DDIS. Feldman (1989) describes sensemaking as an opportunity “for organizational members to understand and to share understandings about such features of the organization as what it is about, what it does well and poorly, what the problems it faces are, and how it should solve them” (p. 19). Data reflection refers to structures leaders build to helps their school make sense of which problems to address and to set goals for the instructional program. These occasions for reflection can take place at the district, across the school, or within the school in grade-level or content area groups. We found two kinds of data reflection in our schools: data retreats and faculty meetings. Schools typically engaged in one or two whole school and/or district data retreats sponsored by the district or another outside agency and provided multiple structured opportunities to reflect on data over the course of the school year during regularly scheduled meetings.

Data retreats provide the opportunity for large groups within districts and/or schools to make sense of achievement data and to set organizational goals. Data retreats require schools to assemble a variety of data, to discern patterns in what they have assembled, then to generate hypotheses and action plans to address these concerns (Sargent, personal communication). Two of our schools engaged in district-led data retreats just after the close of the school year. Attendance was voluntary, although one district arranged for college credits to encourage teachers to attend. The Walker school district, for example, used its data retreat to tie data reflection practices into their annual “visioning process”. The district administrator explained how, once they identified the issue, they then began to examine more data to determine contributing factors to how this came to be. This “deeper” reflection, as he calls it, came only after the initial recognition of the problem:
We also dug deeper and said ok, of those people who are not performing to at least 20 or so, what kind of classes are they taking? We found out that the boys are taking lower level classes and they're taking fewer core academic classes than the girls. Collaborative reflection on the data helped them narrow the problem of student achievement to a question of gender equity, and led to discussions about how to resolve the issue in terms of the instructional program.

We found that retreat leaders were quite directive in their efforts to lead reflection. This tension between directed agendas vs. open exploration of the data characterized the degree to which the retreat is a forum for announcing results or an invitation to solve problems. One district leader explained how they tried to resolve this tension at the district data retreat:

Our philosophy is not to do the PowerPoint and then say, “Okay guys, get to work.” Or come over and do the work for them, you know? We feel as though it’s more powerful if we give them what the task is and then let the teachers and principals at the building level dig into it and have their own conversations. We may ask leading questions, [but] we want them to have the “ah-ha!” themselves.

A district administrator shared his observations of how different principals in his district led subsequent school-reflections:

(In) one of the elementary principals … allowed the staff members to lead as much of the discussion as possible. … I think he was the most successful- the one's where the principals pretty much ran the show, they ran everything. Once (the teachers) got into their small groups, (they) were the most dysfunctional…. The teachers felt a disconnect, didn’t feel a part of the results. There’s a fine line between having your principal lead and having the teachers help themselves.

The outcome of the data retreat is to develop district goals for teaching and learning. One Walker district administrator explains how the goals develop:

We found these positives, we found these negatives, you know, as a result of that, they take that information and then they review it and then that's the first thing that you need- just to lay all of your ideas out and things out and you have all of that information over the summer and then the next time we meet, we
narrow down- I use different methods each year to narrow it down. So we narrow down what we feel is critical goals for the district and that's basically what we do and we end up with 4 or maybe 5 at the most, district goals because I think if we get over that many, you're never going to achieve them.

The departments and schools in the Walker district are then expected to derive their local goals from the district’s overall goals. These goals must be measurable, attainable, and relevant, and they are subsequently reviewed by the board of education:

[E]ach department will have a set of goals that are in a lot of cases related to the assessment. . . . 50% in each math quartile will meet or exceed an individual growth targets by evidence of the fall and spring performance. . . . So data is driving one of the goals in that building- and you can look through the rest of this and find the same thing. . . . [In] social studies . . . they're talking about areas of concern on the (state exam) and grade point averages. So they're looking at data to make decisions about improving instruction and that's their goal for the year that they're going to be targeting—certain things that really relate to assessments that they do and that we do.

Local data reflection activities. While the district data retreats helped to determine district-wide learning goals, each of our schools structured a number of occasions to develop local goals and to plan for how to meet the district goals. On average, we observed four data reflection sessions during the year in each school. These reflection sessions addressed data disaggregation, item analysis, and charting individual student progress. Data disaggregation activities at the school level began with breaking achievement data down to the individual student level, which then allowed teachers to relate additional sources of behavioral and social data to understanding achievement results. We found the overwhelming majority of discussions about achievement data focused on helping struggling students achieve proficiency; few discussions concerned how to raise student achievement from proficient to advanced levels. We also found that teachers were more engaged in discussions about individual students rather than grade-level or subject-matter level groups. In each of the schools, the formal leader took responsibility for shifting discussions from individual student interventions to programmatic implications.
The school-level reflection sessions relied on simple graphs and tables of achievement data. The value of data reflection did not seem to rely on the sophistication of the analysis but in the frank discussions of practice and the ability of the staff to identify areas for future effort that result from the conversations. The local data reflection sessions also involved different groups of staff members. Pearson school, for example, used professional development time for “implementation days” that involved the whole faculty in discussing student achievement and student behavior reports. In addition, the Pearson leaders helped organize separate days for the 5th grade teachers, for example, to reflect on their student’s achievement scores, and voluntary beginning and end of the year days to set and evaluate the school learning plan in terms of achievement data. The inclusion of special education staff in all Pearson data discussions seemed to reflect a strong connection with classroom teachers in which the staff discussed the needs of struggling students together.

Other principals came to develop the school’s capacity to reflect on data from different paths. The Harrison school principal, for example, described how she has developed an increasingly more collaborative system for data reflection that started with a small group of trusted colleagues and progressed to include more staff members:

I did this a couple of years, and my school psychologist did this a couple years with us and with the program implementer, you know the three of us would sit down and actually do some item analysis and pull it out and extrapolate it for the staff and hand it over. That's what we did like four years ago. . . . [B]ut now we're more focused on having the committees do it so that everybody's involved in it, so that's been the push.

The Malcolm school principal convened her administrative team on a weekly basis to review school’s behavior data reports. She then used these meetings and reports to identify emergent issues in the school and to develop strategies to share the academic and behavior data with teachers during regularly scheduled grade level meetings. She shared these data to create a “shared culture around children” and establish “collaborative conversations around kids” particularly to identify “what’s going on or not going on with the kids.” After one such meeting that she described the discussions that result from sharing data with her staff as, “the beauty of data; we can have these conversations.”
Taken by themselves, data reflection activities are opportunities for schools to understand achievement patterns in their schools. When integrated into a DDIS, however, data reflection activities are powerful staging areas for school leaders and teachers to frame the problems they seek to solve through program alignment and design and to develop goals that can be measured in terms of student learning. Data reflection activities in a DDIS help leaders narrow problems to make them solvable. Without identifying and establishing the problems in a deliberate manner, the schools can only hope that their efforts will actually lead to substantive improvement by virtue of good fortune, and our schools cannot afford to bank on fortune alone.

Program Alignment

The program alignment function served two key purposes in the schools we studied. First, alignment activities served a problem-finding purpose that pointed to areas where the current instructional program did not address student learning needs. Second, alignment helped schools understand the degree to which their current programs fit together and addressed relevant content and curricular standards. We also found the function of program alignment stretched the meaning of what we meant by the instructional system. School leaders aligned not only with curricula and classroom materials, but also aligned student services, budgeting, personnel and assessment practices in their alignment function.

To illustrate the dimensions of program alignment, we highlight the case of Harrison school’s decision to adopt Direct Instruction as a school-wide instructional program. Alignment activities served as powerful problem-finding opportunities in several schools. The principal at Harrison described how alignment activities helped her begin to diagnose problems of student learning upon arriving at her school:

So, I started the discussion when I first got here with some of the staff in the fall... in regard to where we needed to go with student achievement and with curriculum. Because the one thing that I did notice was that everybody was doing their own thing, the former principal was not aware of a specific reading program for example, our reading scores were quite low, and our reading
resource teacher wasn't aware of a specific program either... I mean wasn't aware of what programs all of the teachers were using.

In this case, the principal perceived that alignment activities were a condition for creating a system to improve student learning. She used alignment activities to understand, and to help the staff see, how the current program fit together in order to determine an action agenda. She described her process for investigating what the school currently offered:

So I had the reading resource teacher survey the staff, and they were basically all doing different things. There was no consistency within the building—we had wonderful staff, great teachers, hard working individuals, lovely school, great environment, caring community, but there wasn't any consistency with curriculum.

At this point, the principal could have pursued several paths toward building a more coherent instructional program. She chose to address the lack of connection between practice in classrooms across her school by investigating how a comprehensive curricular program could bring coherence:

We did an investigation...I looked for volunteers to go out and look at programs in other schools, go out and do some research, go online, speak to parents—we had parents involved in that—and we basically developed an investigative committee and we went out to various schools. They came back with a great interest in the Direct Instruction (DI) curriculum because they saw it in another school. I had known about it because I came from a DI school, and that was one of the schools that I had sent them to so they could see the great things that can happen with that curriculum. But they were actually the ones that saw it, and they were the ones that wanted to start the program.

A key aspect of DI is that it provides direct, ongoing measurement of student learning in terms of the curricular goals. The decision to adopt DI at Harrison provided powerful occasion for sharing practice, engaging in collaborative professional development and served as the basis for a budding professional community among Harrison teachers.

We found that the principal and staff at Harrison did not see DI as a one-stop solution for student learning issues. Rather, the staff continued to engage in problem-
finding activities within the constraints of the DI program. The decision to adopt DI helped to constrain, but did not solve, the student achievement issue at Harrison. This provides an illustration of our second point of how alignment helps determine the congruence of instructional program with relevant learning standards. With each passing year the staff became increasingly proficient with the curriculum, but they found that not every child was successful on the standardized tests. In order to meet the needs of all children, the Harrison principal explained how the staff began to consider the alignment of DI with learning standards:

In the third year (of DI) we were really focusing on, okay, where are the gaps, .... so we're growing each year as we're learning more and being better at what we're doing. It's been easier and easier each year in regards to understanding how to align it and what materials we may need... Other literature, other books that we bring in, other resources that staff will bring in or teachers will recommend, we'll purchase or provide for staff, we'll develop the supplemental material library for staff, so lots of different resources.

The staff also engaged in on-going alignment activities to determine where the DI program needed to be supplemented to meet the needs of particular student groups:

[F]or example,... with our Hmong refugees that we have,...students that don't know any of the language or speaking or understanding anything about America, let alone being able to say, "Hello" during the day. One of the things that we've been able to do is take a look at some of the specific needs and supplement with some technology, so we've been able to provide some programs too in that area, we've been able to supplement for students' comprehension with like Accelerated Reader too, we use that, we use Math Facts in a Flash, we use some other technology programs to assist in helping with some of the gaps that we find in the regular curriculum, so that's been supportive.

In Malcolm school we observed how alignment activities focused on curriculum and state assessments. This school's district assumes that if curriculum is aligned with state standards, students will be learning what they need to excel on the state exam. The director of curriculum and instruction within the district described his role in the realignment process as follows,
(A)fter the tests are completed, after the results have returned, then my role pretty much kicks in and I do things like (work with the) staff (to) do item analysis of the ….test scores. We make sure that we're teaching the right curriculum that they align their curriculum with the state and in some cases—there is a state standard established by the state associations and so they need to align their curriculums with those components. I make sure that that's fine.

While the district alignment process focuses on how to understand test scores in terms of the state test, school alignment efforts focus on where and how the tested topics are covered in the curriculum. One principal explains:

The state sends us an item analysis, it's kind of a gross overview, and then what I ask the teachers to do is to dig into that deeper and pull out segments so that they can correlate it more tightly with the curriculum….you look at something and you say, "oh, let's go back and look at the curriculum, what are we spending too much time on, what are we not spending enough time on, let's start to dissect this, and let's see how we can approach it differently, and then let's jack it up to the next layer and let's look at our instructional practices."

Here we can see how the line between data reflection and program alignment begins to blur in activities such as item analysis of standardized tests. Principal and teachers use the test items to reflect on their student achievement scores in terms of what they report covering in their classrooms, thus integrating the reflection and alignment functions into a single activity. The Pearson school dedicates 3 full in-service days per year, 75% of their annual professional development time, to session for teachers to disaggregate data and engage in item analysis of the state exams. However, the local expertise required to successfully engage in item analysis is expensive to develop. The Malcolm principal describes how the capacity to engage in this kind of reflection/alignment activity is just beginning to emerge among her teachers:

I would say, if I can be very honest, it's a real challenge, we probably, we are now, and granted this is only the second year, we've really gotten any worthwhile information back, ... I would maybe think I have three people on staff that really are getting an understanding of what that really means, what does it mean to look at this question that 75% of the students got wrong, and
what was the content of that, and what was the standard behind that, ... [Y]ou find a teacher who's doing it well, and you make a big deal about that teacher doing well, that "Oh, you know what, he's really got a good idea here, here's what he kind of came up with for his chart, and go on ask him to talk about it," you know you do that kind of thing, you kind of try to get teachers to teach teachers, because that is by far and away the most effective thing. Now that we've had two years of experience...teachers are getting a better idea.

A final point concerns the alignment of the instructional program with student services, community outreach and additional programs. All the schools we studied have sophisticated special educational placement services to coordinate instructional program services with individual student needs. Other schools have moved beyond typical special education services developed an extensive student behavior programs (Malcolm’s R&R program) to coordinate student support services with the demands of the instructional program. Other schools have developed programs to align instructional offerings with community ESL or adult literacy needs.

Program alignment activities in themselves provide schools with information about the range and organization of their current program. Integrated into a DDIS, however, alignment activities come to life as a “reality-testing” function to inform goals set through data reflection. Building an information flow within schools means that leaders must align programs to determine where resources have already been spent and will need to be allocated.

Program Design

Leaders and teachers use a variety of artifacts to assemble the instructional program of the school. While some artifacts are designed by school members to meet specific instructional needs, others are inherited by the school, and still others are received into the school from district and state contexts (Halverson, 2003). We found two distinct categories of artifacts used to shape the instructional program of the school: *curriculum-based programs* are used to instruct groups of students in terms of conventional classroom settings; *student-based programs* are designed to customize institutional resources to the needs of individual students.
Curriculum-Based Design includes the variety of programs schools use to guide classroom instruction. For the purpose of the DDIS, we found that each of our schools had selected a variety of reading, writing and math curricula to meet the state accountability demands in these subjects. The literacy curricula ranged from comprehensive programs such as Direct Instruction (Harrison), to balanced literacy approaches the required teachers and leaders to customize phonics and whole language approaches to the needs of their students. In math, schools followed their district lead to adopt comprehensive curricular packages such as Everyday Math. All of the schools felt that the comprehensive approach to math had significantly improved teacher capacity and teacher learning, and consequently math had received less attention in the DDIS discussion. Improving literacy scores, on the other hand, continued to prove a stubborn challenge and served as the central topic of data reflection and program design in the school’s DDIS. Program design in science and social studies was left largely outside the purview of the DDIS because, in part, these subjects did not receive the same emphasis from the state accountability system. At Pearson School, for example, social studies and science curriculum were guided a multiple intelligence-based curriculum design process largely outside the DDIS. Groups of teachers met monthly by grade level, using a Lesson Study-like format to collaboratively design and discuss sample social studies and science lessons. These design efforts were reported at faculty meetings, but their results were not discussed with the same attention as the literacy efforts at Pearson.

Program design is also used as a way to provide targeted solutions to specific problems surfaced through the DDIS. To illustrate the use of program design within the DDIS, we consider the reaction of Walker school to revelation that they had failed to meet the 2004-05 NCLB Annual Yearly Progress requirements for special education students in reading. Failure to meet AYP was seen as a public black eye for a suburban district widely recognized for educational excellence. A district curriculum specialist reflected on how he came to understand the achievement problem in special education:

A year ago I thought we were in pretty good shape with special ed reading…on the (state exam), and then we dropped a couple points this year (and) didn’t make AYP.... And last year (2003) our special ed students were ahead of the district standard (of 61% students testing at proficient or advanced on the (state
exam)….This year we’re at 57%, so we didn’t make it by shooting towards that mark. So then we looked at the state, and we had to decrease our lowest group by 10 percentage points.... But... as you know our special ed students can read, we take a look at our students at large and 95% of our kids in the district were at proficient or advanced reading. And that's pretty good, you know, so- we're not sure what to make of it…Our test participation rate was at 100% I think. Our graduation rate was at 95%. …it just doesn’t make sense to me.

Except for reading in special education, the specialist remarked how the overall district scores were well above the state average. Even in special education, he reasoned that most of the children are proficient in reading according to other district measures.

Ultimately the Walker principal and district leaders framed the problem by focusing on finding a received artifact to help raising the achievement of the low performing students by 10% in order to meet the AYP. A district official highlighted Read 180, a pull-out program designed to offer intensive reading remediation through a combination of classroom and computer-aided instruction:

We're looking at a descriptive reading program for low achieving students called Read 180….We found out from last few (state exams) that our low verbal students are not performing to their level of aptitude in reading. So we're looking at this as possibility of having a reading specialist or a classroom teacher or a special ed teacher work with the very lowest score readers. Read 180… has 90 minutes of reading everyday…We're looking to try it (as) a result of looking at our verbal readers not progressing the way that we would want.

After a thorough investigation of the program and its potential for success in improving the reading of special education students is assessed, the district decided to purchase the program. By January teachers were trained to use the program and students were placed in a pilot program. Once received by the school, the principal and staff used achievement data to help place students into a pilot trial period. The Walker principal explained,

We also made a very conscious decision of the kids that we're going to target for the pilot. We used data…I created a template or a table, that took the lexile levels from the kid's most recent math test, I took their reading and writing scores, and I took their reading score percentile on the MAP, but where are they
in the whole big picture thing. ... Then I took their language use percentile, I documented the types of support [the students received], Then I looked at their schedules to determine what would be the least disruptive method of pulling them (out for Read 180)…. (We) took the kids that …would need this the most.

This example illustrates DDIS program design. Selecting programs to address emergent student achievement issues is certainly not new in schools. This tendency toward program aggregation is responsible for the “Christmas tree” phenomenon (Bryk, et. al.) of schools adding incompatible programs the result in incoherent systems of practice. Integrating program design into a DDIS helps schools use student achievement data and existing program commitments as a check for program bloat. The Walker example shows how were used to determine program weakness and target just the right artifact to address the problem.

*Student Based Design* approaches the instructional question from the perspective of individual, rather than collective, student need. Drawing on the powerful precedent of the special education Individual Education Plan (IEP), student-based program design develops systems to develop customized instructional plans for struggling students while avoiding the stigma that often results from special education identification. The goal of student-based design reflected how school leaders and teachers perceived the problem to be solved in student achievement. Leaders at the Malcolm school, for example, felt that student well-being was a critical aspect of improving student learning. Leaders reasoned that students unable to cope with the restrictions of the classroom environment would have a much lower chance to experience success in the instructional program. The Respect and Responsibility Program (R&R) program was designed as a social problem-solving tool, not a discipline tool. A teacher involved in the R&R design remarked, “we might hand out a little discipline (in R&R), a little consequence for the social problem solving issue, but discipline still comes from the principal.”

The R&R program grew out of comprehensive school audit school intended to identify the problems the school was encountering in the initial year of the current school Malcolm principal. The audit resulted in four problem-solving teams – including one dedicated to “climate and order.” This committee proposed both curriculum-based solutions (Life-skills lessons built into the normal instructional program) and R&R, a
student-based program that describes a set of escalating steps for intervention with a disruptive student. The R&R team is comprised of the school psychologist, social worker, an educational assistant, a school facilitator, and the school's assistant principal. A team member is on duty throughout the school day. When a student behaves in a manner that compromises his or her learning and/or that of their classmates, the teacher is expected to intervene. If the intervention is unsuccessful, an R&R team member is called in. The R&R team member helps the student solve the problem with the skills necessary to return to class. Chronic cases of misbehavior result in an intervention process crafted by the R&R team in consultation with parents and the classroom teachers. This intermediate intervention step has helped make the behavior problems of a number of students manageable without special education identification. From a DDIS perspective, the key aspect of R&R is the wide range of student data both generated and analyzed by the staff. All referrals are documented, tallied, and analyzed in weekly meetings by teams of school administration, staff, and teachers. The focus of the analysis is to make sense of the frequency, severity, and patterns of behavior as indicated by the R&R referral system. Both cumulative and student-level behavioral data are integrated into the data reflection process at Malcolm in order to give teachers move beyond test scores to get a handle on the education of the whole student. The effect of the R&R program is to provide the Malcolm DDIS with the information necessary to help teachers make the right adjustments in the classroom:

Every room in this building (has children) with incredible issues -- enough to scare people. But kids still learn, they come and they produce, they have good test scores. Teachers and kids are doing what they need to do in order to teach and learn.

A final aspect of program design is to acquire additional resources for necessary innovations. Each school leadership team has an established record of grant acquisition. However, grants come with their own program demands that are often at odds with existing program requirements. The Harrison principal, for example, described the how taxing a recently acquired federal Reading First grant has been for the school.

It takes a lot of time…There are many additional testing requirements with the grant. Testing takes about an hour to an hour and half to test each child. This
means that teachers could possibly be out eight days for the year just to assess their students twice. Because of the time required I have worked with the district to have retired teachers come out and help test so that not so much classroom instruction is lost. This has helped, but it is has been difficult. We are hoping that we can get assistance in reducing the assessment. Assistant Principal also stated he hoped for changes to help reduce the cost of the assessment. The extra people are cost money.

The key feature of DDIS program design in each of our schools was the staff willingness and capacity to change core instructional programs in light of data analysis and reflection. These schools blended curricular and student-based interventions to customize instructional programs to adequately support student learning. Their experience leads us to believe that exclusive attention to either curriculum-based or student-based interventions can create dysfunctional DDISs in which information does not flow across functions. Simply adding even the most rigorously-tested programs can set up false hopes and failed expectations for student success while leaving the real problem, the inadequacy of the existing instructional program, unaddressed. Similarly, student-focused interventions can lead to widely reported efforts to “game” accountability systems by focusing resources on the students on the verge of success while ignoring the needs of students on either side of the accountability threshold. In the hands of savvy leaders, accountability pressures can result in balanced approaches to program design that can benefit the learning needs of most students.

Formative Feedback

The formative feedback function is perhaps the most critical, and most difficult to implement, aspect of a successful DDIS. Formative feedback structures collect and create occasions to discuss the on-going information generated by teachers and students about the quality of school initiatives. Most schools find it too expensive to develop systematic feedback on current programs, and instead rely on occasional, anecdotal assessments. None of our schools demonstrated the capacity to provide systematic feedback in terms of student learning across their instructional programs. However, several schools provided examples of how such structures have been developed in
specific areas. These examples fall into two categories: artifacts developed by local school leaders and teachers, and artifacts developed or purchased at the district level and adapted by local leaders to school needs.

**Locally-developed artifacts.** The Title 1/Literacy Feedback program at Pearson school provides an excellent example of a system designed by local school leaders to provide systematic feedback on program initiatives. Pearson school is in a rural district with limited resources that forces the district to stretch personnel across schools. (The Pearson principal, for example, is also the principal of five smaller rural schools.) The Pearson leadership team has had to rely on re-purposing in-house expertise to provide feedback on program design. The principal worked with the Title 1 teacher over time to develop a sophisticated system to measure the effect of literacy program design on student learning. The Title 1 teacher, a veteran reading specialist with training in Reading Recovery, worked with teachers for six years to redesign the Pearson K-2 reading program. The cornerstone of the literacy program was Guided Reading (GR), an early childhood program that helps early reader develop of effective strategies for processing text at increasing levels of difficulty (Fountas and Pinnell, 1996). GR relies on running records, individualized, on-going formative student assessments, to help teachers organize groups for reading activities. The Pearson Title 1 teacher organized her schedule to spend time working with groups of students teachers in each classroom in order to get a sense of teacher’s practice and student performance. She began assembling binders of running records information to track student progress over time, and worked with teachers to supplement the GR assessments with formative feedback tools from Reading Recovery and other programs such as the district-supplied Developmental Reading Assessment (DRA). The Title 1 teacher commented: “collecting data on how much kids understand and where their understanding breaks down helps us understand where they need more help. This gives our kids a chance to feel comfortable with what they are doing so they can say “I am a reader.””

Taken together, these data provided a powerful resource for measuring program quality. Still, the data themselves would not provide formative feedback unless teachers would use the information in their instruction. Pearson’s leaders realized the value of structured opportunities for reflection in making formative data useful. The Title 1
teacher described meeting weekly with every teacher and monthly meetings with the k-2 teachers and special education teachers to discuss and disaggregate the data. “Data disaggregation time lets us discuss our children and our program. (In our discussions) we also look at home life – we know that when families go through a divorce, children lose a year of academic progress. We also look at the data (during) mid-year meetings and during our (school-wide) implementation days.” Professional time dedicated to data discussion helps develop a strong professional community around literacy instruction. These discussions help identify problems with the existing program. For example, in the early days of Pearson reading program, teachers were unknowingly using different vocabulary to describe the Guided Reading program to children:

When we started, we found that one teacher was saying ‘sound it out’, another teacher was saying ‘stretch it out’, another said ‘say it slowly.’ Our top kids were figuring it out, but the kids who were struggling were saying ‘I gotta do something else?’ They didn’t get it…We have a common language now. Once they established a common language, the struggling readers could figure out that the skills sought by different teachers were the same.

This complex system of formative measures serves several key functions in the Pearson instructional program. First, it helped Pearson staff develop a shared ownership of transformed practice. Although K-2 teachers continue to work in classrooms, they feel more connected to each other’s practice through participation in the Guided Reading assessment system. Second, this professional community has helped staff to use the formative feedback as an effective measure of program design. When teachers began to realize that Guided Reading was not addressing the needs of several students, one teacher shared her experienced at an Orton-Gillingham phonics-based program workshop. After several other teachers attended the workshop, the Pearson team began to integrate Orton-Gillingham activities and assessments into the literacy program for selected students. Finally, the formative assessment program has helped staff anticipate the results of the state exam. The Title 1 teacher described how she is “rarely surprised, because the running records help to determine where the children should be on the DRAs, which predict the (state exams) well.”
Adaptation of received artifacts. Other DDIS schools relied on district-initiated programs to develop similar feedback systems for early reading initiatives. The Malcolm school works with the district’s Gateway to Literacy program, which also relies on teachers keeping running records, to provide feedback for their balanced literacy initiative. A Malcolm teachers describes the effect of the program in the school:

So it’s no longer okay to say… 'this child is just slow and struggling,' Really taking the responsibility and saying 'I need to figure out what I can do differently because obviously what I’m doing isn’t working.'

Malcolm teachers have found the data provides through the Gateways program valuable for guiding their instruction:

A teacher had a whole (first-grade) reading group stuck on a pretty beginning level…They weren't making progress, so we looked at the (teacher’s) running and we realized that several of the kids in that group were decoding- they were trying to make sense but they didn't know the high frequency words that most kids just know like this… So we designed a new program to get those kids more practice with high frequency words and it was because the teacher had running records of that and we could actually see that it in their writing samples too.

The Gateways project helped this teacher used formative data to pinpoint student struggles design a new approach that would better serve those students.

Harrison’s Direct Instruction program also generates formative data through brief literacy assessments such as DIBLES (Dynamic Indicators of Basic Early Literacy Skills) to feed back into the instructional program. The structure of the DI program itself provides a framework to measure how well the program is being implemented. The Harrison principal describes the tools provided by DI to keep track of program progress:

The DI chart (helps us) collecting the data weekly, compile it, and put together a monthly Critical Index (that) I look at, typically. I don't look at the weekly data myself as much…unless there's a thing that's alarming or I need to address a teacher…or if something wasn't completed…. Like right now I have a real concern about our Language for Learning in the K-4 classes, because they're not progressing as quickly as they should be, they're not learning what they need to be right now.
The MAP program at Walker school serves a similar function of providing on-going information on student achievement to inform program design. The MAP tests generate immediate reports about how students are progressing toward state standards across subject areas according to computerized adaptive tests. However, leaders must create opportunities for teachers to reflect on these data in order to make the information useful. Rebecca Blink’s (2005) work describes how one district used the MAP data to structure professional development and program design sessions across schools literacy and math. The Walker leaders are currently developing structured opportunities for teachers to use the MAP data in similar ways.

The tools described above are used to generate information about program success in terms of student learning. There are several other tools available to school leaders to build formative feedback for teachers into the DDIS. One obvious path is to link teacher evaluation into the formative feedback process. Unfortunately, the current conflation of formative and summative functions makes it difficult to untangle these functions in practice. Nevertheless, the schools we studied developed several methods to provide formative feedback for teachers. Each school has invested in instructional coaches to provide formative feedback for teachers while leaving summative evaluation to the school principal. Harrison’s Direct Instruction program uses a literacy coach to help teachers adjust practices in light of formative data. The Harrison principal spoke literacy coach’s value in assembling and distributing data:

Having a literacy coach is really good… she's the one person, quite honestly, where all these worksheets go. If there's any red flags, (she brings it) to my attention and I'll address it, or then on a monthly basis it's put together as far as an overall, which each classroom, which each group, how they're improving, where they're going, are they making enough gains.

In addition, Walker school leaders encouraged teachers to develop action research projects to generate feedback about program initiatives as a path for teacher professional development.

Formative feedback structures are both pervasive and difficult to identify in most schools. Leaders need to build such structures to generate information for teachers to adjust their instruction in terms of student learning need to build structure. Even though
these practices are expensive and difficult to institutionalize, the net effect of successfully implemented formative feedback structures is to transform classroom practice by tightening the coupling between administrative and teaching and showing how information loops can inform as well as evaluate practice.

Test Preparation

Test preparation evokes images of teachers drilling students on irrelevant test questions for hours on end – bypassing the instructional program in order to engage in the dreaded “teaching to the test.” In an era of testing and accountability, the simplistic reduction of the debate between “testing as savior” and “testing as evil” does not hold in the presence of current expert practice in schools. We observed a variety of test preparation activities that supplemented, rather than supplanted the instructional programs at our schools. We organized our findings into four categories of test preparation activities: curriculum embedded, test practice, environmental design and community outreach.

Curriculum embedded approaches to test preparation describe how leaders and teacher integrate the conceptual content of standardized tests into the regular instructional program. This strategy hinges on the argument that what is tested is worth learning in schools, with the corollary that what is tested can, if necessary, determine the range of taught content. As one principal explains, embedding standardized content in the curriculum is an outcome of the a design strategy for aligning curriculum, standards and evaluation:

We honestly provide them with the curriculum that the board has approved and you know, our logic is that if the test is aligned to the standards and our curriculum is aligned with the standards, and the curriculum is aligned with the test. Then the curriculum is aligned with the test, and we should be fine.

Another principal described how integrating the tested content into the curriculum helped students make a seamless transition from course content to tested content.

Just by teaching them appropriately every single day in class, that’s how they are prepared. We’re going to teach them the best way we can every day in school and hopefully that will get them where they need to be with testing.
In data disaggregation and item analysis meetings across schools, we saw how teachers and leaders related exam and lesson content. At Pearson School, for example, teachers were particularly interested in understanding how the problems surfaced through testing could be translated into lesson design. In fact, the Pearson school data reflection discussions were marked by contrasting agendas: the principal emphasized analyzing the results of testing, while teachers consistently moved from the results to how they could address the emergent issues in their classrooms. These discussions, and others, demonstrate how test preparation could be seen as a microcosm for the DDIS process taken as a whole.

*Test practice* focuses on helping students become familiar with the structure and format of the test through practicing of test taking skills outside of the regular classroom curriculum. Test practice ranges from actual practice on similar tests to making sure students have an understanding of what the test structure will be. We discovered that our schools focused on developing test taking skills rather than test drill: One principal declared: “we don’t teach them the test. Research has shown it’s not an effective way to get students to do well, and so we are not going to waste our time with that.” The schools have developing testing skills in several ways. One school provides classroom teachers planning time while another teacher teaches a specific testing skill to her class; another has created a program in which some skills preparation is done specifically by guidance counselors in a *Middle School and Beyond* program.

*Environmental design* employs strategies to creating a conducive environment for students during testing events. This environment not only includes what is done on the day of testing, but events leading up to testing. The strategies we observed included grouping students, organizing the testing environment, proctoring and creating an exciting and healthy for the tests. One principal discussed how she and her staff use grouping strategies to prepare students for testing:

When we're testing, we'll do small groups. Some will be whole class, but in other situations we will have…special ed kids or ESL students, a small group with a specialist or an educator. And that time during testing…it's usually like a two-week period in November, we will cancel all of our specialists (responsibilities) and they will assist with testing. So it's a school-wide effort,
all the teachers lose their assistant time. So everybody in the community is involved, and assists during testing time.

Student grouping also provides room for the school to use special testing strategies allowed by state regulations, such as reading exams aloud or providing unlimited time spans for certain groups of students to finish the exams.

Coordinating a proctoring schedule is another environmental design task for the leadership team. One principal noted how encouraging teachers from across the school to proctor helps staff understand the rhythm and the demands of testing on children as well as the content of the test. Another principal discussed she prepares the proctoring plan:

I'll go through it with my assistant principal, he'll go through it with her (program implementer), but she's the gatekeeper of that, she's the one who really manages the groupings and things like that. And the teachers help, obviously--she asks for input, first of all, from the teachers. You know, who would see, who do you feel would need a small group, and then she gets that and compiles that information and then figures it out from there.

Some schools try to create an exciting and healthy atmosphere for testing to help children understand the importance of the test. One school held a pep-rally with the high-school cheerleaders and band to kick off testing week, then provided healthy snacks and slippers for students to feel comfortable with the often grueling exam process.

Community outreach practices refer to how a school informs their school community about testing requirements. Now that schools are held accountable for standardized testing results, leaders in our schools have created artifacts to facilitate communication with parents and the community. Here one official describes district outreach efforts:

Well have newsletters that go home to parents…(that give) strategies to help. We say (what) we've done at school for test preparation….We talk about the superficial “get your kids to bed at a certain time” so we let parents know…when the testing is, when the tests are coming up …. (One) principal there has a meeting at the beginning of the year with the parents- I think its the first day of school…(to) explain the district's priorities (and) the building's goals for the year, what testing things we need to work on, what she would like
done to help with that…. (Our) belief is that testing and its importance must be communicated from day one to the parents and school community. Back-to-school and teacher conference nights also provide opportunities to prepare the community for testing. Teachers at one school explained how they have developed reports based on a combination of state exams and their formative tests to explain student performance in terms so that parents will understand reports of school performance in the local papers.

Discussion and Conclusion

This preliminary run through the data we have collected over this past year has helped us clarify the DDIS conceptual framework and understand how well the framework describes data-driven decision making practices in schools. The DDIS was able to capture a range of activities leaders and teachers use to translate achievement scores into classroom level information. The transition we observed between DDIS functions helped leaders to reduce the data, to understand what it meant, and to design and measure interventions for improving teaching and learning. We saw how teachers played a key role across the DDIS in pushing the data toward creating useful information in the classroom, and how formal leaders worked to keep school-level questions of student achievement at the forefront of the discussions. Moving back and forth between classroom and school level uses of data seemed to both rely upon and create the conditions for vibrant professional communities in each school.

There are two areas for further investigation we would like to mention: subject-matter leadership and the influence of special education practices. We found significant subject matter differences in the capacity to use data for instruction across schools. In language arts, each school had developed a sophisticated, formative assessment model to gauge student progress through the school’s language arts curriculum. The capacity to generate useful data for teachers on student learning also seems to have sparked strong professional communities around language arts instruction in each school. The story in math was different. We have collected evidence that schools are considering achievement data in math, but we have not seen the same commitment to local program design and collaborative commitment to formative assessment that we found in language
arts. Each of our schools followed a district initiative to adopt a common math curriculum (Direct Instruction math in one school, Connected Math in another, and Everyday Math in the remaining two). We observed little evidence of data use or professional community around the complexities of math teaching or learning. The math curriculum, however, is discussed in several of the schools as a form of outreach through workshops for parents to experiment with math concepts with their children. Science instruction received less attention than either language arts or math. Indeed, even when schools discussed other topics in terms of data disaggregation and item analysis sessions, teacher tended to treat science and social studies topics in terms or reading comprehension and vocabulary familiarity. One school addressed science education as a part of a larger district initiative; another used a general curriculum design process to guide grade-level development of social studies and science projects; in another schoolteachers talked about science in terms of the comprehension sections of the state exam. Understanding how subject matter influences the capacity to use data for instruction will be a central interest for our next round of research.

Special education practices also seemed to act as a template for organizing student-level program interventions. Each school had developed procedures to continuously generate data on program effectiveness. The action plans they develop upon realizing where students are falling short, however, seem to be organized for individual students on a special education student identification model. The prevalence of the familiar IEP (Individualized Education Program), student-based intervention model helps school leaders and teachers focus their efforts on how to help individuals, but may not address the systemic causes of why the students are learning as they are. Even in the aspects of the program with strong evidence of data use, faculty discussions about remediation tend toward the level of “how can we help this individual student” rather than “how is our program leading toward this type of learning.” While the special education precedent may make discussions of student achievement more manageable, focusing accountability discussions on student-level rather than program-level issues may lead leaders to bypass the need for systemic overhaul. Critics of testing have commented on how student-level reactions to accountability can lead to gaming the system by focusing on students on the cusp of proficiency rather than on the needs of all students.
We observed an interesting balance of curriculum-level and student-level interventions across our schools. Schools seemed to settle on program-level interventions then use student-level programs to fine-tune program adequacy. Without feedback loops to integrate individual student interventions back into the program, however, the two levels of design could operate independently rather than as complementing pieces of an instructional system. Exploring the pervasiveness of the special education metaphor may tell us much more about the constraints and affordances of processes schools develop to use data for instruction.

We also found it difficult to develop a clear, one-to-one relation between functions, artifacts and practices in the schools. The functions of the DDIS rarely occur in isolation, and are linked together in complex organizational practices. One hypothesis could be that, from a design perspective, these functions might have originally corresponded to specific artifacts, but as the DDIS became a mature system, the functions began to merge together across reflection, alignment and design activities. We felt it was important to disentangle these functions for the purpose of guiding new leaders in building the pieces of a DDIS in their schools, but we need to do more work to determine the degree to which these functions were or should be linked together in received or created artifacts. Our effort to understand the independence of artifact functions reflects our bias as researchers. Taken individually, the functions we described here characterize much current research in school organizations and leadership. Indeed, each function of the DDIS exists as a separate research specialization in academia. In future work we will need to delve more deeply into what has already been discovered in each of these specialized But researchers have the luxury to abstract from the messy contexts of practices that practitioners do not enjoy. Faced with the challenge of making improvements “all at once”, practitioners need to understand how functions can be assembled into systems that generate their own self-correcting feedback.

“Teaching to the test” has long been a phrase used to criticize the role of testing in schools, implying that the content of schooling will be “reduced” to formulaic instruction. It is clear from our data that leaders have constructed multiple artifacts to link the instructional program to the content and structure of the tests. However, the DDIS we observed in action did not appear to have the characteristic of “reduction”.\"
rather, we observed rich instructional systems in the process of being redesigned to help children learn in terms of state standards as measured by state exams. The phrase “teaching for the test” is a better description of DDIS assembly. Understanding how the pieces of the DDIS link together to facilitate an information flow for improving student learning gives both researchers and practitioners a more holistic sense of how the pieces fit together to comprise the central tasks of the new instructional leadership.

Appendix A
DDIS Interview Protocol

1. **Overview of school programs:**
   - Which programs has the district/school invested in to improve the quality of teaching?
   - Which programs has the district/school invested in to improve the quality of learning?
   - What kinds of teacher committees and leadership committees exist in the school?
   - What kinds of student support services are provided in your school? (e.g. Special Education, ESL, Talented and Gifted programs, etc.)
     1. Are these programs integrated into the regular school program, or are services provided outside the regular classroom?

2. **Data Acquisition:**
   - What kinds of data do you rely on for improving learning?
   - Describe the ways in which your school acquires information about student learning.
   - Who works with those systems? Who helped build the systems, and who helps maintain them?

3. **Data Analysis:**
   - What practices or events guide the school community to make sense of achievement data?
     1. Are there established occasions to discuss disaggregated data? Are disaggregated data presented at the student level? At the classroom level? At the school level?
     2. Are there occasions for teachers and staff to engage in item analysis of standardized tests?
   - Which faculty and staff discuss data? How are these discussions structured?

4. **Curriculum Alignment:**
   - What efforts have been made to align instructional programs with learning and assessment goals?
   - What materials and resources do you provide or use to guide curriculum alignment efforts?
   - Who builds and maintains these materials and resources?

5. **Instructional Design:**
   - Is each teacher held responsible for improving instruction to meet learning and assessment goals?
   - Are there structures in place for teachers (at grade level or subject level) to collaboratively design instruction to meet learning goals?
   - What are the main instructional design initiatives in math? In Science?
Who initiates and monitors instructional design efforts?

6. **Formative Feedback:**
   - How do teachers and leaders know whether their instructional design efforts are effective?
   - Are there programs or structures in place that use feedback to reshape teaching and learning?
     - i. In math?
     - ii. In science?
   - Who develops and maintains feedback practices?

7. **Test Preparation:**
   - How are children prepared for testing?
   - What processes and resources structure preparation practices?
   - Who builds and maintains these processes and structures?

8. **Conclusion:**
   - Are there other insights/ideas/observations that we missed in our interview that you would like to share about data use in your school?
Appendix B
DDIS Coding Scheme
Revised 7/7/05

**Data Acquisition**—“Processes used by schools to seek out, collect, and prepare information to guide teaching and learning.”
- Process
  - Collection—
  - Storage—from filing cabinets to data warehouses
  - Reporting—formal or informal reports, responses to queries
- Agent (code in addition to process)
  - Internal—done by the school
  - External—done by an outside entity, such as district, state, Northwest Evaluation Association

**Data Reflection**—“Structured processes to engage the school community in making sense of student learning data that result in goals for improving teaching and learning.”

Question: What’s going on? Focus on the students.
- District led
- School led
- Grade-level led
- Content Area led

**Program Alignment**—“Program alignment processes make the school’s curriculum congruent with relevant content and performance standards as well as what is taught in classrooms in order to improve student learning.”

Question: What do we need to change? (generally will use multiple codes)
- Standards—set by district and state
- Practice—what is taking place in the classroom
- Curriculum—what is to be taught
- Assessment—how student progress is measured

**Program Design**—“How a school acts on perceived instructional needs through the creation or adaptation of curricula, pedagogies, student service programs and instructional strategies in order to improve student learning.”

Question: How are we going to change? (Always code for source in addition)
- Curriculum-focused Design
- Student-focused Design
- Source
  - Local Design—modified or created locally
  - Received—bought or given from outside
  - Inherited—pre-dates the principal
Formative Feedback—“Learner-focused iterative evaluation cycles designed to create ongoing timely flows of information used to improve both student learning and instructional program quality across the school.”

Question: Are our changes working as we want them to?
- Program Level
- Administrator Level
- Teacher Level
- Student Level
- Positive Feedback

Test Preparation—“Activities designed to motivate students and to develop strategies for improving performance in taking state and district assessments.”

- Community Outreach
- Embedded in Curriculum
- Environmental Design
- Test Practice
